

Social, Economic and Cultural Overview and Assessment for Ocean Management

Review and Analysis of Global Practices

Executive Summary

The approach taken by the Department of Fisheries and Oceans towards an integrated approach to oceans management, and the development of Integrated Management Plans for Large Ocean Management Areas (LOMAs), requires attention to both ecosystem aspects and social, economic and cultural considerations. In this context, “the goal of integration is to move beyond treating social, cultural and economic issues and concerns as additional or peripheral considerations toward a more proactive process that includes these objectives as drivers and integral parts”. This report on Social, Economic and Cultural Overviews and Assessments (SECOA) for Ocean Management is one step in a project, led by the Department of Fisheries and Oceans, to address these objectives.

This report reviews international examples of frameworks and methodologies that have been, or are currently being, used to collect and assess socio-cultural and economic information relevant to marine management. In this report, an analysis is carried out of 16 case studies representing examples of (1) several analytical frameworks, as well as several one-time studies, (2) varying geographic scales, but with a focus on regional and/or ecosystem-based planning activities, and (2) a range of countries and contexts, but emphasizing examples that can most easily be transferred to a Canadian context.

Case studies were identified and selected using a combination of approaches that included (1) expert opinion, based on correspondence with national and international experts in this area of interest; (2) literature reviews and (3) assessments based on a set of characteristics of a Large Ocean Management Area (LOMA) as defined by Fisheries and Oceans Canada. The first tier of case studies (the most relevant LOMA-scale) includes the South East Marine Region, the Russian Arctic, the Great Barrier Reef, the Scottish Coast, the Northwest Forest Plan, the Cod Grounds, Port Stephens and the Channel Islands. The second tier includes two groupings: large-scale multi-country case studies (Baltic Sea, Benguela Current LME and Greater North Sea) and small-scale case studies (San Salvador, Tortugas, Montego Bay, US Virgin Islands, Vaavu Atoll). These second tier case studies represent a “step up” and a “step down” in spatial area, when compared

with a LOMA; however they were selected because they illustrated specific approaches or lessons learned that could be useful to a SECOA.

This report outlines the methodology used in the review and provides a summary and analysis of the main findings, as well as general observations and evaluations of the case studies. A companion document provides an in-depth review of each of the report's 16 case studies, with each case study portfolio presented using a uniform format.

Overall, the case studies may also be seen as falling into two main groups in terms of the approach taken. Some were nested within a larger analytical framework and/or planning process; in these cases, our analysis involved reviewing the framework first, to contextualize and describe how the case study fits into the “bigger picture”, before examining the case study itself. For another set of case studies, socio-economic assessments were carried out, not necessarily as a component of a national integrated planning process, and based on their own unique framework or methodology. In all cases, the objectives, project duration, funding source (where applicable), data description and methodology used for data collection and analysis are examined.

Among the limitations faced by the review team was the diversity within and across the case studies (in terms of planning phase, location, objectives, etc.) which made comparisons, “measuring success” and identifying “best practices” difficult. The time factor also constrained a more in-depth analysis and inclusion of other case studies. Given that there were very few examples that the team could draw on as “a good example of a SECOA at a LOMA scale”, the team spent some time defining the parameters and constraints of this review, in consultation with Fisheries & Oceans staff and a consultant, and drawing on information provided by a set of experts.

As a final point concerning the approach used in this report, we note that the analysis of the case studies (as described in the companion document) include discussions of potential strengths and limitations of each case study, which include assessments both by those involved in the case studies themselves, and as interpreted by the present authors

within the context of what might be applicable to a Canadian situation. Unless stated otherwise, the latter points as well as the overall observations given at the end of this report, are the views of the present authors.

Based on the case studies reviewed, the following trends are identified:

Data sources and methodologies: 84% of the case studies used only secondary data, with the main source being statistical agencies, government departments and previous studies. Questionnaire surveys, interviews with key experts, focus groups and meetings were the main mode for the collection of primary data. Economic evaluation models, combined with mapping and GIS analysis, were the main forms of data analysis used in the selected case studies.

Identification of commonly used variables: At the LOMA scale, all eight case studies included an overview of the broad economic situation, including information on employment, income and industry profiles. Cultural considerations appeared to be divided into information on indigenous populations and national historical sites. Social information included demography, education and training, health and resource use conflicts. Governance factors related to applicable legislation and institutions. At the multi-country scale, there were similar economic and social factors as in the LOMA-scale case studies, except that cultural considerations were rarely assessed, which may have been a reflection of the large areas covered in these specific case studies. Governance factors were mainly limited to international conventions, rather than national policies and legislations. Small-scale case studies had similar social and economic factors to the other case studies, but governance factors also included community management, participation and issues relating to access rights. Although culture was not a notable explicit feature at this small-scale level, that may have been because cultural aspects in these localized areas were already embedded in the assessments. Two general overall trends noted were: (1) social data in the form of demographic data was included in all the case studies and (2) the depth of information collected is generally inversely proportional to scale.

Core Elements of a SECOA: Based on the information gleaned from the case studies, a set of “core elements” were identified, reflecting the minimum level of information that seems to be required for conducting a SECOA. Under the social component, the core variables include demography, education and training, health and community services and coastal-ocean use patterns. Economic variables identified included employment, macro indicators such as GDP, available utilities, industry profiles (notably the fishing sector) and housing. Cultural variables included indigenous traditions and heritage. The principal governance variables included structure, traditional/Aboriginal governance and enforcement/security. Although these lists reflect the more commonly occurring of the variables, the sum of these should not be interpreted as indicating a “best way” to conduct a SECOA. In reality, the approaches used and the depth of data collection will depend on local conditions, human and financial capacity, time and political constraints, as well as the objectives of the assessment. A SECOA must be adapted and its process modified to reflect all of these *relevancy factors*, including both spatial and temporal considerations.

Attribute Analysis: The attributes of a SECOA were divided into process-related, content-related and data-form components. It was apparent that each socio-economic assessment possesses different characteristics depending on its objectives, phase, time, budgetary and operational limitations – as above, these *relevancy factors* are crucial to consider in terms of how applicable a given case study is to a LOMA context. In terms of specifics, economic data was usually more in-depth than social, cultural or governance information. Interestingly, approximately half of the case studies flagged current and/or emerging threats that could affect the management area; this aspect could be of particular importance to LOMAs, e.g., in the face of climate change and privatization of rural areas.

Overall observations: The main trends that appeared to emerge for *process-related* points were: (a) cross-scale vertical and horizontal linkages are important when undertaking a SECOA at the scale of a LOMA, (b) the agendas of the agencies leading a SECOA may influence the short-term and long-term success of the work, and future implementation aspects, and (c) community involvement, especially in decision making, can help with the success of a SECOA, and furthermore, the team leading the SECOA

also needs to establish a process where feedback to the community and stakeholders that have contributed to the process can be undertaken, if trust is to be built between the different partners and stakeholders.

The main points in terms of *content-related* factors were: (a) governance factors underpin many of the social-economic and cultural aspects that are contained in a SECOA, so these variables also need to be included when doing the assessment; (b) given the large spatial scale of a SECOA, having a number of representative characteristic sites could provide a way to balance assessment costs and address data deficiency issues, and (c) building on work that has already been undertaken by communities or other partners could be a less conflict-prone way towards meeting common objectives, while reducing expenses and building trust. However if this strategy is to be successful, the approach used to engage partners, share ownership of the project and integrate the different interests and components, should be done respectfully and not be rushed.

Data form trends that emerged included: (a) the diversity and complexity of LOMAs, including the jurisdictional complexity, imply that a “one size fits all” approach is not appropriate; while the creation of national standards would be useful, to ensure that broad categories of information (and key variables) are included and suitable methodologies are followed, it would not be helpful to specify at a national level too much detail in terms of the particular information (e.g., sub-variables) that must be collected in all LOMAs; (b) GIS mapping and maps are useful tools to analyze the information collected, both for government use as well as to produce and present back to the community meaningful results in a user-friendly forum, and (c) in the early phases of planning, long-term monitoring and evaluation processes need to be developed and budgeted, to support a SECOA program.

Finally, it is highly recommended that the SECOA team receive guidance and training in conducting a SECOA, in both the field (community and stakeholder approach, sensitivity and practicality) and analysis components (data storage, analysis, presentation) prior to the commencement of the assessment.

In conclusion, this report has sought to determine, based on reviewing a set of case studies, some of the key ingredients and minimum essentials that might be needed to conduct and support a SECOA. However, two points should be highlighted. First, locating or obtaining the information required to conduct a SECOA, at the scale of a LOMA, is bound to be challenging in practice. Second, undertaking a SECOA at the scale of a LOMA is rare globally, and could be considered “cutting edge” work. In this context, Canada may have the opportunity to be a leader in this area, at the same time taking on the responsibility of sharing the information and lessons learned both at home and with other countries and regions.

A. Charles, M. Winterbottom, L. Wilson and S. Mills (2007). *Social, Economic and Cultural Overview and Assessment for Ocean Management*. Acknowledgements

The team would like to acknowledge the support and assistance received from Megan Sikaneta and Darren Williams (Department of Fisheries and Oceans, Ottawa); Scott Coffen-Smout and Melanie MacLean (Department of Fisheries and Ocean, Halifax); Larry Hildebrand and Mike Milloy (Environment Canada) and Alison Evans (CoastalPlanners). We would also like to thank Robin Mahon, Richard Kenchington, Marcus Haward, Silva Salas, Robert Pomeroy, Yvan Breton, Denis Bailly and all the other experts who provided valuable advice that helped guide this review. The team also appreciates the supporting work done on this project by Sara Pullen. We are grateful to Saint Mary's University and to the Marine Affairs Program, Dalhousie University, for providing logistical support.

Glossary

Commonalities: Variables and sub-variables appearing in two or more case studies.

Framework: An umbrella term encompassing integrated planning processes and broad methodologies for conducting socio-economic assessments (or, more broadly, SECOA analyses).

One-off Case Studies: For the purposes of this report, one-off case studies are defined as overviews and/or assessments that have been conducted on an *ad hoc* basis, that do not follow a particular generic framework or methodology.

Participatory: Stakeholders, including outside researchers, community groups, resource users and other interest groups, are involved, and all learn from the process.

Process-Oriented: The focus is on the *process* of collecting information, so that the learning mechanisms may be as important as the information obtained.

Product-Oriented: The focus is on producing an information report for an agency or for one or more groups of stakeholders.

Socio-economic Assessment: A study of the social and economic, (and possibly also the cultural and policy) conditions of individuals, groups, communities and organizations. Assessments are generally conducted at the start of a project to help better understand the situation and to establish baseline conditions.

Socio-economic Monitoring: A regular process over time, usually at a set of intervals, and following an initial assessment, in order to measure changes and observe whether the project is meeting its objectives. Assessment results will help define the monitoring parameters, but because monitoring is repeated regularly, fewer parameters will be measured than the initial assessment, and these may change as the project continues.

Relevancy factors: The temporal, spatial and operational factors that may influence the success of the project or program; key relevancy factors include the objectives of the assessment, the phase of the assessment, human and financial capacity, political and operational realities, and time and budget for the assessment.

1.0 Introduction

The move of Fisheries and Oceans toward an integrated approach to oceans management, and the development of Integrated Management Plans for Large Ocean Management Areas (LOMAs), requires attention to both ecosystem aspects and social, cultural and economic considerations. DFO outlines the context for this report as follows:

“The past two years have seen the development of Ecosystem Overview and Assessment Reports, and ecosystem and conservation objectives. In order to successfully develop relevant objectives, however, it is also necessary to conduct social, cultural and economic overviews and assessments in the LOMAs. It must be noted that the goal of integration is to move beyond treating social, cultural and economic issues and concerns as additional or peripheral considerations toward a more proactive process that includes these objectives as drivers and integral parts. Social, cultural, economic and ecosystem objectives should be considered comprehensively as interconnected parts of a complete Integrated Ocean Management Plan.”

The aim of this report is to conduct an international review of existing case studies, frameworks and methodologies of social, cultural and economic data gathering, overviews, and assessments relevant to marine management. In doing so, this report (1) covers various geographic scales but maintains a particular focus on regional and/or ecosystem based planning activities (2) includes examples from a range of countries and contexts, but concentrates on examples that can most easily be transferred to a Canadian context and (3) includes some generic works in order to help frame the discussion, but attempts to keep the approach as practical as possible, focusing on insights into real examples.

The studies examined herein come from a range of situations and with a range of terminology. For example, a common term is that of a “socioeconomic assessment”. According to the Socio-Economic Manual for Coral Reef Management (Bunce, et al., 2000), such an assessment is a way to learn about the social, cultural, economic, and political conditions of individuals, groups, communities, and organizations. Bunce et al. (2000) note that there is no fixed list of topics examined in a socioeconomic assessment, but the most commonly identified topics include: gender, resource use patterns, stakeholder characteristics and perceptions, market attributes for extractive and non-extractive uses, market and non-market use values.

As the conditions within each LOMA are vastly different relative to one another, the compilation of case studies herein is intended to be as diverse as possible so as to provide a “toolbox” of different perspectives and various options from which to pick and choose. It must be highlighted, however, that the relevance of each case study is dependent on various operational factors such as time, budget and capacity as well as contextual factors such as the enabling environment in which the assessment was conducted.

It is also worth noting that examples of social, economic and cultural assessments in large-scale marine management initiatives have been quite difficult to come by and it seems apparent that a study of this scale has not been undertaken before. While the concept of assessing social, cultural and economic dimensions is anything but new - there are plenty of studies telling us that they need managing and that the need is urgent – there are few legislative and administrative mechanisms that provide for demonstrably sustainable use and conservation of biodiversity in the same package and as co-equal objectives (Kennington, *pers. comm.*).

1.1 Report Format and Presentation

This report presents the methodology, summary and analysis of the main findings and general conclusions from the study. A companion document (available on request) presents the portfolios and corresponding evaluation for each case study analysed.

2.0 Methodology used in this review

2.1 Data Collection

2.1.1 Expert Consultations

The first step of data collection involved the compilation of a list of expert contacts, people with rank, experience and knowledge who can provide extensive insight on socioeconomic issues and initiatives throughout the world. Over email, the contact persons were asked for their thoughts on examples of processes, assessment frameworks or case studies of spatial management that consider the human dimension in their planning and execution. It was emphasized that terrestrial examples as well as work of any scale (i.e. ranging from a

Large Marine Ecosystem to a typical MPA) would be of interest. This list is presented as Appendix A.

2.1.2 Literature Search

An Internet-focused literature search was undertaken in September 2007, drawing to a considerable extent on sources and feedback from the above-noted experts. Websites reviewed include but are not limited to:

- Government agencies and institutions (e.g. National Oceanic and Atmospheric Association; Canadian Department of Fisheries and Oceans)
- Non-governmental organizations (e.g. The Nature Conservancy; The World Wildlife Fund; Conservation International)
- International institutions (e.g. United Nations Environment Program; the Food and Agriculture Organization)
- Universities (e.g. University of Rhode Island; University of British Columbia)
- Major donors (e.g. the Global Environment Facility; the World Bank)

In conjunction with the electronic search, relevant hard copy materials (e.g. handbooks) either provided by the experts or found in libraries were also examined and reviewed.

2.2 Analytical Frameworks & Case Study Selection

In order to assess the suitability of case studies, an intensive process was undertaken. To ensure the information presented was relevant to a LOMA context, potential case studies were evaluated against seven LOMA characteristics (extracted from DFO background material - see Appendix B); based on this, eight case studies were selected as of highest relevance. While these case studies could be further sub-divided according to spatial scale, this was not done here, to keep the sample size higher during the analysis phase.

The remaining case studies, considered second-tier in terms of relevancy, were grouped according to spatial scale, with one group representing assessments involving multiple countries and the other focusing on reports based on local sites. These case studies can be considered a scale up and a scale down from LOMAs respectively. While they may not be as directly relevant to a LOMA context as the first-tier case studies, they still offer

important lessons that should not be overlooked. The groupings of case studies are depicted in Figure 1a and their geographical location is presented in Figure 1b. It should also be noted that where expert contacts referred us to particular case studies, every effort was made to include their recommendations (refer to Appendix B)

Some of the case studies appeared to be baseline assessments with the objective being to provide a general background and context for further developing a management plan (e.g., the Scottish Coast). Other case studies seem to be further along the planning timeline, leading towards the establishment of a management plan (e.g. the Cod Grounds and Channel Islands assessments) or the multi-scale large area management programs set within a broader national bioregional planning framework (South-East Marine Region). The North West Forest and the Great Barrier Reef case studies are interesting examples of the process required for conducting evaluations and revising established management plans using social-economic indicators and approaches. The former study evaluates the success of a 10-year forest management plan whereas the latter example emphasizes the process undertaken for the revision of “use zones” within the marine park.

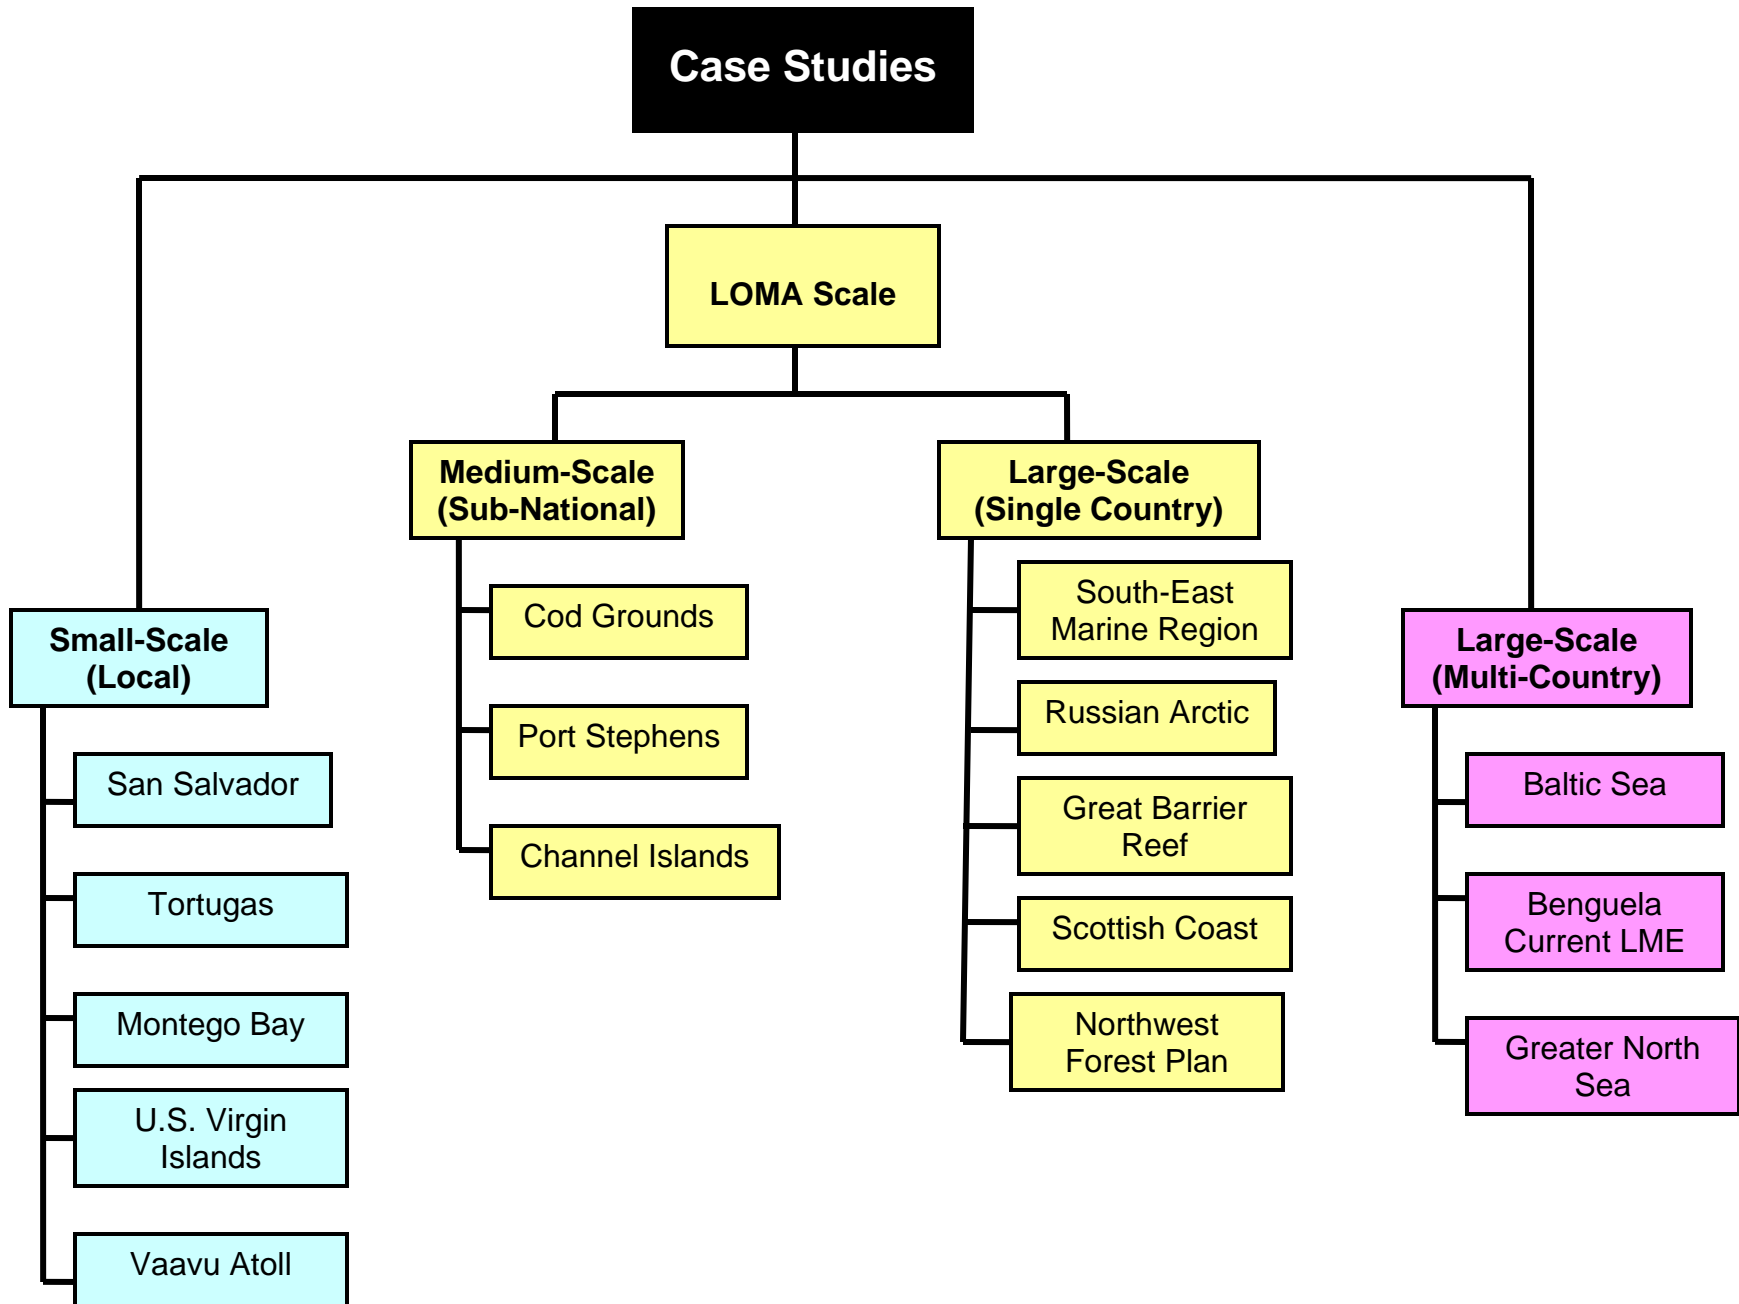

Figure 1a: Grouping of case studies according to relevance to a LOMA

Figure 1b: Geographical location of the 16 case studies (source: <http://chuma.cas.usf.edu/~juster/volc1/world%20map.gif>)

2.3 Case Study Format

Each of the 16 selected case studies follows a uniform format, consisting of two sections.

1. Framework Overview

Certain case studies are nested within a larger planning process and this report attempts to contextualize and describe how these case studies fit into the “bigger picture”. In this report, two integrated planning initiatives are reviewed:

- Australia’s Bioregional Planning;
- Scotland’s Integrated Coastal Zone Management Planning

Some socio-economic assessments are not necessarily a component of a national integrated planning process, but are conducted by NGOs or industry as part of a large-scale project. These assessments often follow established frameworks and/or methodologies. This section also attempts to explain the “raison d’etre” and clearly outline the assessment procedures of the following frameworks:

- Socio-economic Impact Analysis (SEIA)
- Global International Waters Assessment (GIWA)
- Socioeconomic Manual for Coral Reef Management (SocMon)
- OSPAR Quality Status Reports
- Large Marine Ecosystems (LME) 5 Module Approach
- U.S. Northwest Forest Plan

2. Practical Overview

This section provides in-depth examinations of real examples, i.e. already completed socio-economic overviews and/or assessments, and involves a particular focus on process in order to tease out the specific data types, sources and gathering methods used. The “areas for future consideration” component involves an evaluation of the study’s strengths and limitations as related to a SECOA context, based primarily on our general impressions; however, where available, those listed in the report itself were also included. The case studies are drawn from examples of the integrated planning initiatives and frameworks listed above, as well as relevant one-off studies.

2.4 Challenges and assumptions for this review

The large scope of this undertaking, in terms of the wide breadth of variables that can be considered, combined with the diversity of case studies examined, created both an opportunity and a challenge for the project team in narrowing down a portfolio of potentially-useful components and considerations. In addition, trying to define “best practices” was difficult because of the variability and diversity of the case studies. For example the complexities involved in assessing successful or best practices in these case studies are demonstrated by the Port Stephens case study. Although primary data was noted as not being used in the particular report examined (thus being a limitation, because the process did not appear to have engaged the stakeholders), upon closer examination it became clear that the document in question was actually the third report in a series that drew on the baseline primary data that had been collected in an earlier report. However, this case study did note the difficulties in using the earlier report because it was a) done in adjacent areas similar but not identical to the Port Stephens area of interest, and b) done after a marine park and its boundaries had been established which differed from the Port Stephens case where boundaries had not yet been established.

Other noted challenges and assumptions that were made while doing this review included:

- (1) Social-economic assessments, although framed in this manner, tended to be more economic in nature. Cultural components were seldom included explicitly; this may have been a reflection of either a) other reports having been done separately but contributing to this planning phase or b) the embedding of cultural considerations implicitly within the assessment, in situations where local indigenous people are the majority community.
- (2) Within the 16 case studies, there was a vast array of project objectives, tailored specifically to the local conditions in which the assessment was conducted. In other words, “success” was difficult to define and gauge as it could be viewed either in terms of the assessment meeting its own objectives or in terms of the assessment including similar information to a SECOA, thereby making it more relevant and/or useful to the present study.
- (3) Being a review of global practices, the case studies represent a wide geographic distribution; and there are significant differences in the enabling environments of each

setting which could act to either support or limit the particular study. Furthermore each case study employed different methodologies and, for the most part, collected different information variables. Consequently this made comparison of assessments across case studies both qualitative and subjective.

- (4) Not all of the socioeconomic assessments used in the case studies were in the same phase of implementation. For example, some were baseline studies which acted as an initial scoping exercise; others seemed to be a phase ahead and included assessments and detailed analysis of the data collected (these tended to be part of a larger study that involved a series of reports and/or was set within a wider planning framework); a few studies (e.g. Great Barrier Reef and Northwest Forest Plan) were in a monitoring and evaluation phase and, consequently, were collecting different information. Both the type of information and what the information is used for differ from phase to phase, which again made comparison across all case studies subjective.
- (5) The limited time available for this study constrained the range of cases that could be examined and the level of analysis that could be performed.

3.0 Results and Analysis

To assess and compare the case studies, all the data used (including the variables and sub-variables) were compiled into a master database, using Microsoft Excel (refer to Appendix C). The data for each group (i.e. small-scale, LOMA-scale and large-scale) was then filtered, extracted and aggregated into tables of common categories to facilitate comparison. Based on these tables the data were mined and subsequently analyzed.

3.1 Data Sources and Methodologies

Data collected is either as primary, secondary or a combination of both. Secondary data includes information from literature reviews of relevant published and grey material as well as other sources such as websites and databases. Primary data includes information collected from the field through approaches such as face-to-face interviews, telephone and postal surveys, expert and public focus groups and traditional oral documentation; for example, the South-East Marine Region used community workshops and focus groups to obtain primary data.

Figure 2 outlines the distribution of primary and secondary data used across the different case studies. The South-East Marine Region, Montego Bay, Tortugas Ecological Reserve and Vaavu Atoll were case studies that utilized a healthy combination of both primary and secondary data. Although all of the case studies used secondary data, some studies built on earlier primary data that had been collected from either the specific management area in question or similar/adjacent areas. This is particularly the case where the assessment was part of a larger series of studies (e.g. Port Stephens Marine Park). From the case studies reviewed, it was abundantly clear that secondary sources were more widely used for socio-economic assessments than primary sources (84% versus 16% respectively) as depicted in Figure 3 below.

Figure 2: The distribution of primary and/or secondary data within the 16 case studies.

Figure 3: Percentage of primary and secondary data used in the 16 case studies.

3.1.2 Data Sources

From this fairly small sample size of case studies, it seems that socio-economic data is most commonly obtained from statistical agencies (i.e. U.S. Census Bureau etc.), with 13 of the 16 case studies using some form of census information (Figure 4). Census data potentially offers the greatest depth in time and consistency in methodology, and many other research reports and international agencies rely on these government sources for their data. The next most frequented sources included government departments (other than government statistical agencies) as well as previous research studies and review reports (11 of the 16 case studies). These assessments range from government commissioned studies for particular decision making processes to studies by industry, consultants, NGOs and academic researchers.

Although these data sources often provide greater detail regarding specific issues, human populations, or localities, they are often one-off studies with less than consistent methodologies (e.g. Montego Bay). Furthermore, as they are rarely repeated, they lack the consistency that can be provided by census data and similar information from statistical agencies for temporal comparisons. The down-side to census data is that it is seldom collected annually, hence the information may restrict short-term timeframe comparisons; however, this approach does provide a relatively cost effective way to obtain information for profiling social-economic components for the area or community of interest.

Another type of secondary data source is studies that bring together socioeconomic data from a variety of sources to produce a more multidimensional report on current socioeconomic conditions in a specified locality (e.g. Northern Sea and the Benguela Current case studies). Peer reviewed journal articles, industry reports, specialist working groups, research

institutions, and inter-governmental agencies such as the Food and Agriculture Organization (FAO) are examples of such sources that are used to compile these regional assessments. Other examples of secondary data sources include web-sites and maintained data bases, GIS information such as maps and satellite images and grey literature from NGOs and other civil society organizations.

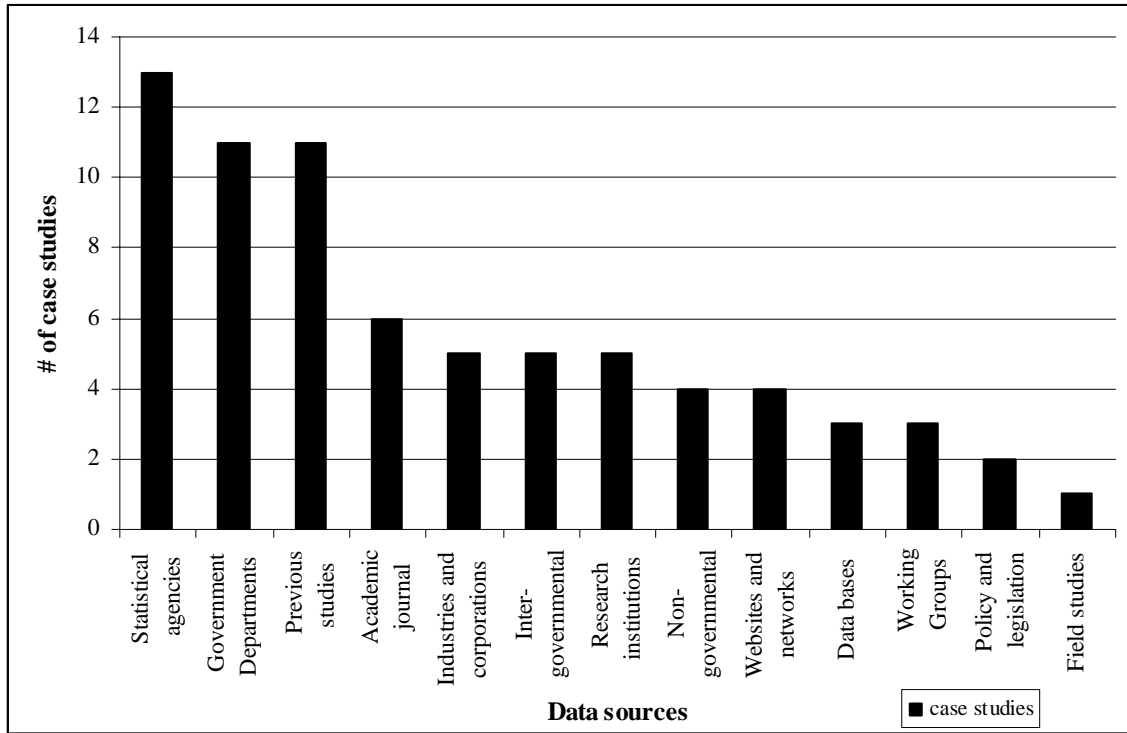

Figure 4: Secondary data sources used in the 16 case studies

3.1.3 Data Collection

The main form of collecting primary data in these case studies was through questionnaire surveys, interviews with key experts, focus groups, meetings and workshops. A summary of the approaches used is provided in Table 1. The recent IOC Manuals and Guides (2006) and monitoring guides by Pomeroy et al. (2004), Wahle et al. (2003) and Bunce et al. (2000) provide good examples of indicators and methodologies for collecting and analyzing social, economic, governance and cultural components in the context of both primary and secondary data.

3.1.4 Data Analysis

Within the case studies, several different analytical methods were utilized to evaluate the data, including but not limited to:

- Economic evaluation models that incorporate both boundary analysis and risk models to determine the impacts to communities and industries by the different alternatives and scenarios being proposed.
- Total economic valuation models and assessments (specific to Australia)
- Mapping and GIS analysis supporting the above analysis.
- Operational costs and the complexity of navigating jurisdictional frameworks. For example, Channel Island and Tortugas Ecological Reserve case studies noted the implications of complex jurisdictional frameworks associated with conducting a boundary analysis of the proposed marine park boundaries.
- The Port Stephens and Great Barrier Reef case studies discussed the costs to government for establishing the marine park and the implications of purchasing commercial fishing business buy-backs.

3.1.5 Observations on data sources and methodologies

Based on the case studies reviewed, the following points arose:

- Baseline studies used mainly secondary data to first scope out the context of the study (Great North Sea, Baltic Sea and Scottish Coast). Potential benefits of this approach are the reduced expenses and, in some cases, shorter research timeframes.
- Most assessment and evaluation studies used both primary and secondary data (e.g., South-East Marine Region, Cod Grounds and North West Forest). These studies also tended to be more complex and required longer timeframes, and perhaps involved additional human and financial resources.
- Multi-country and regional planning assessments were reliant on aggregated data from national sources, which required the collaboration and cooperation of the participating in-country offices. Potential issues associated with this approach include language and translation challenges, differences in methodologies, confidentiality and official clearance, incorporating “grey literature” (sourcing and incorporating un-published reports and papers) and intellectual property rights (indigenous communities). This

may be a common issue for large-scale multi-country regional planning and, in the context of a LOMA, these factors may also need to be considered.

- Implications of the different stages or objectives of specific case studies will also need to be considered within the availability of human and financial capacity and project timelines. For example the San Salvador and US Virgin Islands case studies, although not specifically at a LOMA scale, suggest approaches for rapidly assessing social-economic factors in coastal and marine-resource-dependent indigenous communities.
- As with all quantitative and qualitative socioeconomic data, the relevance, limitations and possible biases of the data and the objective of the study should be carefully considered. For example, economic measures such as GDP are known to omit important economic activities such as the underground economy and small-scale subsistence practices which are important elements in considering community well-being.
- Similarly, changes in crime statistics have been critiqued as being more a reflection of changes in statistical practices, police enforcement measures and the willingness of victims to report crimes than objective measurements of the number of crimes being committed.
- The limitations of socioeconomic data suggest that management decisions should not be made based solely on currently available data. Current data will provide an excellent background for meaningful consultation with communities living within LOMAs but potentially may only in general terms capture the effects of some management decisions.
- Although funding agencies were noted in the case studies, few if any reports documented the costs for undertaking these studies and the number, roles and expertise of the people involved. This could have been helpful for considering future planning, capacity and operational costs for LOMAs.

Table 1: Summary of primary data collection methods used in the case studies

Country	Case study	Description
Australia	Cod Grounds Marine Protected Area	Interviews (25) – with owner operators of fishing businesses, employees of fishing businesses who work on the boat, partners in fishing business who don't work on the boat, family members of owner operators or employees, fish cooperative managers, fish cooperative retail outlet lessee.
	South-East Marine Region	Community Assessment: Interviews with 250 marine-related, community-interest groups (non-commercial) and 1300 individuals from a stratified random sample of coastal community.
		Community Assessment: 30 key regional and national conservation organizations and government representatives were interviewed
		Community Assessment: Commonwealth and State managers were interviewed
		Indigenous Assessment: Indigenous Working Group were interviewed Indigenous Assessment: Personal communication
Jamaica	Montego Bay	Interviews (52) - with persons familiar with, and knowledgeable about, one of the three user groups
Maldives	Vaavu Atoll	Interviews with reef stakeholders
		Interviews with civil servants
Philippines	San Salvador	Surveys: random sample of 42 fishing households
		Interviews with village leaders, members of fishers associations and others who have worked at the site
South - Western Africa	Benguela Current	Interviews (6) - with officials familiar with marine industrial activities and issues in the Benguela Current region
United States	Channel Islands	Individual interviews using questionnaires
		Focus group (Fishermen Associations)
	Tortugas Ecological Reserve Study Area	Sea Web 1996. National Sample of 900 U.S. Households 10-15 May, 1996
		Environmental Opinion Study, Inc. National sample of 804 households conducted 18-26 May 1991.
		Telephone interviews
		Focus groups (2) – representatives of fishers (30) and water sports operators (5)
		Telephone surveys (8) – conducted of hoteliers for hotels that border the Park and/or who have expressed a particular interest in Park management
	Personal and staff observations and field notes	
	North West Forest	Interviews with 223 members of 12 communities associated with the sample forests, and 82 agency employees working on the four forests were the source of these qualitative data.
		Interviews were the main source of data for evaluating progress in agency-citizen collaboration under the Plan, and evaluating how effective the Plan has been in protecting forest values and environmental qualities associated with older forest and aquatic ecosystems.
Virgin Islands	Stakeholder surveys	
	Personal communication with key informants	

3.2 Identification of Commonly Used Variables

3.2.1 Methodology

Using the database of raw information from the case studies (refer to Appendix C), the first level of analysis involved data mining to identify *commonalities* in data used within each grouping of studies, based on frequency. This information was placed into tables, one for each case study grouping (small-scale, LOMA-scale and large-scale respectively). These tables (Tables 2-4 below) thus show those data variables and sub-variables that are most commonly used in the case studies, for each particular case study grouping. It must be noted that where cells in the sub-variable category appear empty, this does not imply that no information was collected; rather, it reflects a lack of commonalities across case studies, simply suggesting that different sub-variable information was chosen in the various cases to represent that particular variable.

3.2.2 Preliminary Analysis: Commonly Used Variables

LOMA-Scale

- Both the Port Stephens and Great Barrier Reef assessments included an economic valuation of Ecosystem Services, but also coupled this with an attempt to measure ecosystem values (i.e. how important the ecosystem services are to people). This approach is particularly useful in terms of justifying and setting priorities for decision-making and policy development.
- All 8 of the case studies included an overview of the broad economic situation (including information on employment, income, utilities etc.). This acts to establish a basic understanding of the enabling economic environment, which is often a major root cause of social problems and cultural degradation.
- The majority of the assessments involved individual profiles of all the major industries operating in the area such as oil & gas, tourism, marine transportation (e.g. Russian Arctic, Channel Islands, Great Barrier Reef, Scottish Coast and South-East Marine Region). However, more sector-based approaches (i.e. focused on a single major industry) were also used; in the case of the Cod Grounds and Port Stephens, the fishing industry (both commercial and recreational) was the primary focus, while forestry was the major industry considered in the Northwest Forest Plan.

- While the level of detail and types of data collected differs markedly in the various industrial profiles, there were several common sub-variables that seemed to surface including (1) the value of the industry to the economy; (2) the number of people employed in each industry and (3) the industry's annual total production.
- Cultural considerations appear in several case studies (e.g. South-East Marine Region, Great Barrier Reef, Russian Arctic and Northwest Forest Plan) but to varying extents. For example, in the South-East Marine Region, an extremely in-depth indigenous assessment was carried out, evaluating traditional relationships and rights, aspirations, impacts of colonisation etc.. On the other hand, in the Russian Arctic, cultural considerations included some demographic statistics for indigenous peoples accompanied by a basic overview of traditional activities.
- Aside from information on indigenous populations, the next most common form of cultural data relates to national historic sites such as shipwrecks and archaeological remains, national parks and protected areas and so on (Scottish Coast, South-East Marine Region, Great Barrier Reef).
- Governance data appeared intermittently throughout the case studies and, where it did, it generally involved listing applicable legislation and relevant institutions (government agencies, NGOs, community and environmental organizations, etc.).

Multi-Country

- The assessments at this level tend to be quite broad and usually attempt to paint a general picture of each of the countries involved. As such, macro-indicators such as GDP are heavily relied upon. These may not accurately portray what is happening at lower scales.
- At this scale, cultural variables are rarely considered in assessments. Given the enormous areas in question, there may be too many distinct populations to consider properly. Also, the area of interest in these assessments is vast and predominantly open-ocean; cultural ties to the marine environment often are coastal in nature (due to accessibility issues), so it is possible that cultural influences are not exerted as strongly at this level.
- Governance aspects considered in the large scale assessments tend to take on the form of listing relevant international conventions rather than national policies/legislation.

Small-Scale

- The lack of cultural variables in the table of small-scale studies does not indicate that culture was not considered in these studies, but rather that there were no explicit variables in common between the studies. Because several of these assessments were conducted in remote, localized areas (e.g. San Salvador fishing village, Montego Bay, Vaavu Atoll, U.S. Virgin Islands) the entire essence of the assessment was rooted in the local culture. Since at this level, cultural considerations are innate and permeate into every aspect of the human dimension, it thereby makes it difficult to extract “variables” for assessment.
- Being a table of *common* variables, the depth of information collected at this local scale is not accurately reflected. For example, in San Salvador, fishers were surveyed to ascertain, amongst other things their attitudes towards the distribution/sharing of responsibility for fisheries management and their willingness to support a similar project in the future - because this information is so tailored to the local context, it tends not to show up in a meta-analysis such as this. However, the specific information that was collected is outlined in detail in the case study summary tables provided in the companion document.

General Trends

- Social data primarily takes the form of demographic data, which is consistently included in the case studies, no matter the scale of analysis.
- The depth of information collected is generally inversely proportional to scale: as the scale increases, the level of detail decreases.

Table 2: Identification of commonly used variables for LOMA-scale case studies

Data Type	Variable	Sub-Variable (if any)
Social	Demography	Population

3.2.3 Core elements of a SECOA

Table 5 presents the “core elements” of a SECOA – data which the results of this report’s analysis indicates are most important to accurately and thoroughly carry out an overview and assessment. This provides an overall sense of how others have focused in terms of the human dimensions of ocean management. Selection of these elements was based entirely on the case studies, which involved reviewing Table 2-4, re-assessing the raw data (see Appendix C) and a data mining exercise to draw out commonalities between all of the case studies, regardless of their grouping in earlier analyses. As such, this table represents those data variables and sub-variables used in all spatial scales of social, economic and cultural assessments. This aggregated analysis, while to some extent seeming to compare “apples and oranges”, enables the integration of the smaller and larger scale studies, as well as LOMA-scale studies, to draw overall lessons. In terms of process, sources of data and collection methods drawn from the case studies are listed alongside the core elements, as potentially suitable options for future studies.

It should be noted that while this list indicates commonly-occurring variables used in overview and assessment studies, there is no “best” way to conduct a socioeconomic assessment. The order of the steps and data collected will vary widely depending on local conditions, capacity, budgetary and time constraints as well as the objectives of the assessment (Bunce et al. 2000). Moreover, socioeconomic assessment should be adapted, and its process modified, to the particular situation and context.

3.3 Attribute Analysis

3.3.1 Methodology

Based on the “areas for future consideration” section within the assessment of each case study (in the companion document), a suite of characteristics or attributes of socio-economic assessments was formulated and these were then grouped as process-related, content-related and data-form related. Each case study was subsequently evaluated in terms of the presence or absence of each attribute; however, it is important to note that no judgment was made (i.e. the presence or absence of the attribute was not viewed as a strength or limitation, simply a characteristic).

3.3.2 Attribute patterns

Although there are potential general trends, this attribute analysis demonstrates the complexity of trying to assess different case studies firstly, in terms of their usefulness to the SECOA and, secondly, in the context of the limitations and gaps as defined in the actual reports. This is a key point: the absence of a certain attribute in a given case study (e.g. “lack of stakeholder participation”) may appear to be a ‘gap’ from an external perspective, but not necessarily when assessed against the objectives of the case study. Including the attribute may not have been an original objective, and the case study may have indeed been successful in meeting its overall goal. Consequently, this analysis is distinct from but linked to the idea of a Gap Analysis. Figure 5 outlines some of the possible patterns across the case studies. These include:

- Each socio-economic assessment possesses different characteristics depending on its (1) objectives, (2) phase, (3) time, and (4) budgetary and operational limitations - these *relevancy factors* make some case studies more applicable to a LOMA context than others;
- The process-oriented case studies tended to be the most intensely and extensively participatory;
- Those socio-economic assessments at small scales tended to be the most participatory;
- Social and economic data were collected in all case studies, but the economic data was generally more detailed and comprehensive, while social data was largely relegated to demographic statistics.
- Only two case studies (Russian Arctic & Benguela Current) addressed potential human health issues. This is surprising given that human health plays an important role in shaping social well-being which, in turn, influences economic output.

	Process						Content								Data Form

Figure 5: Analysis of Case Study Attributes

- 6 out of the 16 case studies discussed user conflicts in the management area. This is an important aspect to include, as an understanding of the reasons for conflict may have significant policy and management implications.
- Approximately half of the case studies flagged current and/or emerging threats that could potentially affect the management area. This is relevant to a LOMA context, particularly in the face of climate change and privatization of rural areas.

4.0 Overall Observations

This section provides a set of observations and opinions of the study team, representing the key messages arising out of the analysis of the case studies, as seem applicable to Canadian efforts to undertake overviews and assessments of LOMAs. Following on from the attributes section, the points noted here are also divided into process-related, content-related and data-form related sub-headings.

Process Related

- Stakeholder participation has the advantage of increasing support for the assessment and its findings, providing access to knowledge, resources and assistance and enabling the assessment team to better incorporate stakeholder concerns. A key assumption is that with stakeholder engagement and more importantly an accepted role in decision making, this approach could potentially reduce future costs for enforcement and surveillance, and support long-term monitoring programs.
- If the decision to collect primary data is made and the communities are consulted, it is essential that this information feeds back into the communities within an appropriate timeframe. Failure to do this discredits the project and personnel in the eyes of the community if they are not able to witness the outputs which they gave their time to help produce.
- It is recommended that horizontal and vertical cross-scale linkages be fostered with other government agencies and relevant institutions. These linkages may offer a venue to share the onerous task of collecting social, economic and cultural information (which can save valuable time) and also avoid overlap in data collected. This implies that in terms of

LOMAs, there is a need to recognize the jurisdictional authority of the provincial governments and work with them accordingly so as to avoid possible conflict.

- The information gathered through the SECOA process should be used to identify opportunities and threats within each LOMA. In this context long-term monitoring parameters need to be defined based on the assessment results (while noting these will be different in each Region).
- Agendas that drive these assessments also need to be considered – such as whether the initiative is being led by a Government Agency, donor, NGO or an alliance of multiple stakeholders. The collaboration and support by stakeholders and communities for such an undertaking may be influenced by the specific agenda of the lead agency and could either enhance long-term support and sustainability or foster short-term success, which weakens once the funding or political support at the top-level, is withdrawn.

Content

- Information on governance should be included as part of a SECOA as it exerts a large influence on the surrounding enabling environment. An understanding of the underlying legislative/policy foundation is crucial to understanding how certain social, economic and cultural problems arise and what tools are available to fix them.
- Many of the case studies reviewed placed a heavy emphasis on the “economic” side of things, with much less attention paid to the social-cultural sphere. Attempts should be made to cover all aspects, maintaining as equal a distribution of attention as possible.
- Although most case studies present the social aspect entirely through demographic statistics, measuring quality of life is becoming more noticeable, especially within Australia.
- As LOMAs are massive spatial units, if primary data is collected it will be impossible to include all communities and stakeholders within the area considered, especially given a limited timeframe. From the outset, it is therefore important to identify representative or characteristic study sites that can be used as indicators for the entire region.

Data form

- The diversity across the LOMAs is a reality that should be embraced and, in doing so, a one-size-fits-all approach to conducting SECOAs should be avoided. The creation of national standards would be useful, to ensure that broad categories of information (and certain key variables) are included and that appropriate methodologies are followed, but it would not be appropriate to specify at a national level too much detail in terms of the particular information (e.g., sub-variables) that must be collected in all LOMAs.
- Ideally, a SECOA should involve the collection of both primary and secondary information (while noting that the balance between these relies on the enabling conditions within each LOMA). The secondary data complements the primary data in terms of (a) identifying gaps in existing knowledge in preparation for the field data collection, (b) ensuring the field data collection does not involve information that has already been collected, (c) providing a basis for cross-checking information collected during the field data collection and (d) providing supporting documentation for field data collection (e.g. maps of the study area).
- GIS Mapping could be an appropriate approach to utilize the information collected, both for government use as well as to bring something back to the communities. It also potentially reduces the costs of collecting primary data by incorporating socio-cultural factors within the broader economic and governance framework.
- Long-term monitoring and evaluation plans should be developed and built into the SECOA process in the early phases of planning. This can be accomplished within a short timeframe through training workshops. However, if these initiatives are to be sustainable, follow-up workshops and funding/support networks need to be planned and budgeted.
- Secondary data should be collected at different scales (i.e. national, sub-national and local), while recognizing the limitations and inaccuracies in each set of statistics.
- In the interests of time efficiency and to avoid redundancy, the SECOAs should, where possible, build on existing studies (such as those completed by industry or NGOs).

Capacity building for SECOA teams

- Any socioeconomic assessment will address a broad range of issues across different disciplines and technical fields, including the social sciences, natural sciences, and policy

analysis. Ideally the assessment team will reflect this range. If there are no team members to cover all these disciplines, it does not mean that the socioeconomic assessment cannot be carried out, but the team should be aware of these limitations and try to address them throughout the assessment.

- It is highly recommended that the SECOA team receive guidance and training. This is particularly critical when managers and team members may not feel comfortable with the processes described, do not feel they have the background and capacity to fully understand the methods and processes, and/or are unfamiliar with procedures for updating the community on the results of the studies.

5.0 Conclusions

As coastal and ocean management continues to be developed worldwide, there is an increasing need to understand both the ecological and the human context of such management initiatives. Specifically, in ocean areas designated for management, it is crucial to assess the various social, economic and cultural aspects that form the baseline within which management is to proceed. To that end, the present report has developed and implemented a new approach to enable systematic examination of overview and assessment studies relating to the human dimensions of ocean management areas, particularly at the scale of a Canadian ‘large ocean management area’ (LOMA). The aim is to better understand what has been and is currently being done worldwide, and ultimately to use this knowledge to initiate ‘best practices’ in a Canadian context.

As there has been little work carried out to date in examining the human dimensions at a LOMA scale, Canada can potentially play an important pioneering role. This includes the responsibility to disseminate the results, and particularly the lessons learned, widely enough that the LOMAs can learn from one another, and that these experiences can be shared with other countries, to foster learning on a national and global scale, and strengthen the various international networks that are seeking improved management of the various human uses of the world’s oceans.
